Turmeric (*Curcuma longa*) is extensively used as a spice, food preservative and colouring material in India, China and South East Asia. It has been used in traditional medicine as a household remedy for various diseases, including biliary disorders, anorexia, cough, diabetic wounds, hepatic disorders, rheumatism and sinusitis. For the last few decades, extensive work has been done to establish the biological activities and pharmacological actions of turmeric and its extracts. Curcumin (diferuloylmethane), the main yellow bioactive component of turmeric has been shown to have a wide spectrum of biological actions. These include its anti-inflammatory, antioxidant, anticarcinogenic, antimutagenic, anticoagulant, antifertility, antidiabetic, antibacterial, antifungal, antiprotozoal, antiviral, antifibrotic, antivenom, antiulcer, hypotensive and hypocholesteremic activities. Its anticancer effect is mainly mediated through induction of apoptosis. Its antiinflammatory, anticancer and antioxidant roles may be clinically exploited to control rheumatism, carcinogenesis and oxidative stress-related pathogenesis. Clinically, curcumin has already been used to reduce post-operative inflammation. Safety evaluation studies indicate that both turmeric and curcumin are well tolerated at a very high dose without any toxic effects. Thus, both turmeric and curcumin have the potential for the development of modern medicine for the treatment of various diseases.

INDIA has a rich history of using plants for medicinal purposes. Turmeric (*Curcuma longa* L.) is a medicinal plant extensively used in Ayurveda, Unani and Siddha medicine as home remedy for various diseases^{1,2}. *C. longa* L., botanically related to ginger (Zingiberaceae family), is a perennial plant having a short stem with large oblong leaves and bears ovate, pyriform or oblong rhizomes, which are often branched and brownish-yellow in colour. Turmeric is used as a food additive (spice), preservative and colouring agent in Asian countries, including China and South East Asia. It is also considered as auspicious and is a part of religious rituals. In old Hindu medicine, it is extensively used for the treatment of sprains and swelling caused by injury¹. In recent times, traditional Indian medicine

uses turmeric powder for the treatment of biliary disorders, anorexia, coryza, cough, diabetic wounds, hepatic disorders, rheumatism and sinusitis³. In China, *C. longa* is used for diseases associated with abdominal pains⁴. The colouring principle of turmeric is the main component of this plant and is responsible for the antiinflammatory property.

Turmeric was described as *C. longa* by Linnaeus and its taxonomic position is as follows:

Class	Liliopsida
Subclass	Commelinids
Order	Zingiberales
Family	Zingiberaceae
Genus	<i>Curcuma</i>
Species	<i>Curcuma longa</i>

The wild turmeric is called *C. aromatica* and the domestic species is called *C. longa*.

Chemical composition of turmeric

Turmeric contains protein (6.3%), fat (5.1%), minerals (3.5%), carbohydrates (69.4%) and moisture (13.1%). The essential oil (5.8%) obtained by steam distillation of rhizomes has α -phellandrene (1%), sabinene (0.6%), cineol (1%), borneol (0.5%), zingiberene (25%) and sesquiterpines (53%)⁵. Curcumin (diferuloylmethane) (3–4%) is responsible for the yellow colour, and comprises curcumin I (94%), curcumin II (6%) and curcumin III (0.3%)⁶. Demethoxy and bisdemethoxy derivatives of curcumin have also been isolated⁷ (Figure 1). Curcumin was first isolated⁸ in 1815 and its chemical structure was determined by Roughley and Whiting⁹ in 1973. It has a melting point at 176–177°C; forms a reddish-brown salt with alkali and is soluble in ethanol, alkali, ketone, acetic acid and chloroform.

Biological activity of turmeric and its compounds

Turmeric powder, curcumin and its derivatives and many other extracts from the rhizomes were found to be bioactive (Table 1). The structures of some of these compounds⁴ are presented in Figure 1. Turmeric powder has healing effect on both aseptic and septic wounds in rats and rab-

*For correspondence. (e-mail: ranajitb@yahoo.com)

bits¹⁰. It also shows adjuvant chemoprotection in experimental forestomach and oral cancer models of Swiss mice and Syrian golden hamsters¹¹. Curcumin also increases mucin secretion in rabbits¹². Curcumin, the ethanol extract of the rhizomes, sodium curcumin, [feruloyl-(4-hydroxycinnamoyl)-methane] (FHM) and [bis-(4-hydroxycinnamoyl)-methane] (BHM) and their derivatives, have high antiinflammatory activity against carrageenin-induced rat paw oedema^{13,14}. Curcumin is also effective in formalin-induced arthritis¹³. Curcumin reduces intestinal gas formation¹⁵ and carbon tetrachloride and D-galactosamine-induced glutamate oxaloacetate transaminase and glutamate pyruvate transaminase levels^{16,17}. It also increases bile secretion in anaesthetized dogs¹⁸ and rats¹⁹, and elevates the activity of pancreatic lipase, amylase, trypsin and chymo-

trypsin²⁰. Curcumin protects isoproterenol-induced myocardial infarction in rats²¹. Curcumin, FHM and BHM also have anticoagulant activity^{22,23}. Curcumin and an ether-extract of *C. longa* have hypolipemic action in rats²⁴ and lower cholesterol, fatty acids and triglycerides in alcohol-induced toxicity²⁵. Curcumin is also reported to have antibacterial¹⁵, antiamebic²⁶ and antiHIV²⁷ activities. Curcumin also shows antioxidant activity²⁸⁻³¹. It also shows antitumour³²⁻³⁴ and anticarcinogenic³⁵⁻³⁸ activities. The volatile oil of *C. longa* shows antiinflammatory³⁹, antibacterial^{40,41} and antifungal⁴¹ activities. The petroleum ether extract of *C. longa* is reported to have antiinflammatory activity⁴². Petroleum ether and aqueous extracts have 100% antifertility effects in rats⁴³. Fifty per cent ethanolic extract of *C. longa* shows hypolipemic action⁴⁴ in rats. Ethanolic extract also possesses antitumour activity⁴⁵. Alcoholic extract and sodium curcumin can also offer antibacterial activity^{15,18}. The crude ether and chloroform extracts of *C. longa* stem are also reported to have antifungal effects⁴⁶. A *C. longa* fraction containing ar-turmerone has potent antivenom activity⁴⁷.

Pharmacological action of turmeric and its extract

Several pharmacological activities and medicinal applications of turmeric are known^{1,2,4}. Although curcumin has been isolated in the 19th century, extracts of the rhizomes of *C. longa* have been in use from the Vedic ages^{1,48}. Some of the medicinal applications³ of turmeric are mentioned in Table 2.

Pharmacological action of curcumin

Effect on gastrointestinal system

Stomach: Turmeric powder has beneficial effect on the stomach. It increases mucin secretion in rabbits and may thus act as gastroprotectant against irritants¹². However, controversy exists regarding antiulcer activity of curcumin. Both antiulcer⁴⁹ and ulcerogenic^{50,51} effects of curcumin have been reported but detailed studies are still lacking. Curcumin has been shown to protect the stomach from ulcerogenic effects of phenylbutazone in guinea pigs at 50 mg/kg dose^{52,53}. It also protects from 5-hydroxytryptamine-induced ulceration at 20 mg/kg dose^{52,53}. However, when 0.5% curcumin was used, it failed to protect against histamine-induced ulcers⁵⁴. In fact, at higher doses of 50 mg/kg and 100 mg/kg, it produces ulcers in rats⁵¹. Though the mechanism is not yet clear, an increase in the gastric acid and/or pepsin secretion and reduction in mucin content have been implicated in the induction of gastric ulcer⁵⁵. Recent studies in our laboratory indicate that curcumin can block indomethacin, ethanol and stress-induced gastric ulcer and can also prevent pylorus-ligation-induced acid secre-

Figure 1. Structure of natural curcuminoids.

tion in rats. The antiulcer effect is mediated by scavenging of reactive oxygen species by curcumin (unpublished observation).

Intestine: Curcumin has some good effects on the intestine also. Antispasmodic activity of sodium curcumin was observed in isolated guinea pig ileum¹⁴. Anti-flatulent activity was also observed in both *in vivo* and *in vitro* experiments in rats¹⁵. Curcumin also enhances intestinal lipase, sucrase and maltase activity⁵⁶.

Liver: Curcumin and its analogues have protective activity in cultured rat hepatocytes against carbon tetrachloride, D-galactosamine, peroxide and ionophore-induced toxicity^{17,30,57}. Curcumin also protects against diethylnitrosamine and 2-acetylaminofluorene-induced altered hepatic foci development⁵⁸. Increased bile production was reported in dogs by both curcumin and essential oil of *C. longa*^{19,59}.

Pancreas: 1-phenyl-1-hydroxy-*n*-pentane, a synthetic derivative of *p*-tolylmethylcarbinol (an ingredient of *C. longa*) increases plasma secretion and bicarbonate levels⁶⁰. Curcumin also increases the activity of pancreatic lipase, amylase, trypsin and chymotrypsin²⁰.

Effect on cardiovascular system

Curcumin decreases the severity of pathological changes and thus protects from damage caused by myocardial infarction²¹. Curcumin improves Ca²⁺-transport and its slippage from the cardiac muscle sarcoplasmic reticulum, thereby raising the possibility of pharmacological interventions to correct the defective Ca²⁺ homeostasis in the cardiac muscle⁶¹. Curcumin has significant hypocholesteremic effect in hypercholesteremic rats⁶².

Effect on nervous system

Curcumin and manganese complex of curcumin offer protective action against vascular dementia by exerting antioxidant activity^{63,64}.

Effect on lipid metabolism

Curcumin reduces low density lipoprotein and very low density lipoprotein significantly in plasma and total cholesterol level in liver along with an increase of α -tocopherol level in rat plasma, suggesting *in vivo* interaction between curcumin and α -tocopherol that may increase the bioavailability of vitamin E and decrease cholesterol levels⁶⁵. Curcumin binds with egg and soy-phosphatidylcholine, which in turn binds divalent metal ions to offer antioxidant activity⁶⁶. The increase in fatty acid content after ethanol-induced liver damage is significantly decreased by curcumin treatment and arachidonic acid level is increased⁶⁷.

Anti-inflammatory activity

Curcumin is effective against carrageenin-induced oedema in rats^{13,14,68,69} and mice⁷⁰. The natural analogues of curcumin, viz. FHM and BHM, are also potent anti-inflammatory agents¹⁴. The volatile oil³⁹ and also the petroleum ether, alcohol and water extracts of *C. longa* show anti-inflammatory effects⁷¹. The antirheumatic activity of curcumin has also been established in patients who showed significant improvement of symptoms after administration of curcumin⁷². That curcumin stimulates stress-induced expression of stress proteins and may act in a way similar

Table 1. Biological activity of turmeric and its compounds

Compound/extract	Biological activity	Reference
Turmeric powder	Wound-healing	10
Ethanol extract	Antiinflammatory	71
	Hypolipemic	44

Bisdemethoxycurcumin	Antioxidant	29
Sodium curcumin	Antiinflammatory, antibacterial	18

Table 2. Medicinal properties of turmeric

Turmeric finds medicinal applications in	Anaemia, atherosclerosis, diabetes, oedema, haemorrhoids, hepatitis, hysteria, indigestion, inflammation, skin disease, urinary disease, wound and bruise healing, psoriasis, anorexia, cough, liver disorders, rheumatism, sinusitis
--	---

to indomethacin and salicylate, has recently been reported⁷³. Curcumin offers antiinflammatory effect through inhibition of NFκB activation⁷⁴. Curcumin has also been shown to reduce the TNF-α-induced expression of the tissue factor gene in bovine aortic-endothelial cells by repressing activation of both AP-1 and NFκB⁷⁵. The antiinflammatory role of curcumin is also mediated through downregulation of cyclooxygenase-2 and inducible nitric oxide synthase through suppression of NFκB activation³⁴. Curcumin also enhances wound-healing in diabetic rats and mice⁷⁶, and in H₂O₂-induced damage in human keratinocytes and fibroblasts³¹.

Antioxidant effect

The antioxidant activity of curcumin was reported⁷⁷ as early as 1975. It acts as a scavenger of oxygen free radicals^{6,78}. It can protect haemoglobin from oxidation²⁹. *In vitro*, curcumin can significantly inhibit the generation of reactive oxygen species (ROS) like superoxide anions, H₂O₂ and nitrite radical generation by activated macrophages, which play an important role in inflammation⁷⁹. Curcumin also lowers the production of ROS *in vivo*⁷⁹. Its derivatives, demethoxycurcumin and bis-demethoxycurcumin also have antioxidant effect^{29,30}. Curcumin exerts powerful inhibitory effect against H₂O₂-induced damage in human keratinocytes and fibroblasts³¹ and in NG 108-15 cells⁸⁰. Curcumin reduces oxidized proteins in amyloid pathology in Alzheimer transgenic mice⁸¹. It also decreases lipid peroxidation in rat liver microsomes, erythrocyte membranes and brain homogenates²⁸. This is brought about by maintaining the activities of antioxidant enzymes like superoxide dismutase, catalase and glutathione peroxidase⁸². Recently, we have observed that curcumin prevents oxidative damage during indomethacin-induced gastric lesion not only by blocking inactivation of gastric peroxidase, but also by direct scavenging of H₂O₂ and •OH (unpublished observation). Since ROS have been implicated in the development of various pathological conditions^{83–85}, curcumin has the potential to control these diseases through its potent antioxidant activity.

Contradictory to the above-mentioned antioxidant effect, curcumin has pro-oxidant activity. Kelly *et al.*⁸⁶ reported that curcumin not only failed to prevent single-strand DNA breaks by H₂O₂, but also caused DNA damage. As this damage was prevented by antioxidant α-tocopherol, the pro-oxidant role of curcumin has been proved. Curcumin also causes oxidative damage of rat hepatocytes by oxidizing glutathione and of human erythrocyte by oxidizing oxyhaemoglobin, thereby causing haemolysis⁸⁷. The pro-oxidant activity appears to be mediated through generation of phenoxyl radical of curcumin by peroxidase–H₂O₂ system, which cooxidizes cellular glutathione or NADH, accompanied by O₂ uptake to form ROS⁸⁷.

The antioxidant mechanism of curcumin is attributed to its unique conjugated structure, which includes two meth-

oxylated phenols and an enol form of β-diketone; the structure shows typical radical-trapping ability as a chain-breaking antioxidant (Figure 1)^{88,89}. Generally, the nonenzymatic antioxidant process of the phenolic material is thought to be mediated through the following two stages:

where *S* is the substance oxidized, AH is the phenolic antioxidant, A• is the antioxidant radical and X• is another radical species or the same species⁹⁰ as A•. A• and X• dimerize to form the non-radical product. Masuda *et al.*⁸⁹ further studied the antioxidant mechanism of curcumin using linoleate as an oxidizable polyunsaturated lipid and proposed that the mechanism involves oxidative coupling reaction at the 3' position of the curcumin with the lipid and a subsequent intramolecular Diels–Alder reaction.

Anticarcinogenic effect – induction of apoptosis

Curcumin acts as a potent anticarcinogenic compound. Among various mechanisms, induction of apoptosis plays an important role in its anticarcinogenic effect. It induces apoptosis and inhibits cell-cycle progression, both of which are instrumental in preventing cancerous cell growth in rat aortic smooth muscle cells⁹¹. The antiproliferative effect is mediated partly through inhibition of protein tyrosine kinase and c-myc mRNA expression and the apoptotic effect may partly be mediated through inhibition of protein tyrosine kinase, protein kinase C, c-myc mRNA expression and bcl-2 mRNA expression⁹¹. Curcumin induces apoptotic cell death by DNA-damage in human cancer cell lines, TK-10, MCF-7 and UACC-62 by acting as topoisomerase II poison⁹². Recently, curcumin has been shown to cause apoptosis in mouse neuro 2a cells by impairing the ubiquitin–proteasome system through the mitochondrial pathway⁹³. Curcumin causes rapid decrease in mitochondrial membrane potential and release of cytochrome *c* to activate caspase 9 and caspase 3 for apoptotic cell death⁹³. Recently, an interesting observation was made regarding curcumin-induced apoptosis in human colon cancer cell and role of heat shock proteins (hsp) thereon⁹⁴. In this study, SW480 cells were transfected with hsp 70 cDNA in either the sense or antisense orientation and stable clones were selected and tested for their sensitivity to curcumin. Curcumin was found to be ineffective to cause apoptosis in cells having hsp 70, while cells harbouring antisense hsp 70 were highly sensitive to apoptosis by curcumin as measured by nuclear condensation, mitochondrial transmembrane potential, release of cytochrome *c*, activation of caspase 3 and caspase 9 and other parameters for apoptosis⁹⁴. Expression of glutathione S-transferase P1-1 (GSTP1-1) is correlated to carcinogenesis and curcumin has been shown to induce apoptosis in K562 leukaemia cells by inhibiting the expression of GSTP1-1 at transcription level⁹⁵. The mechanism of cur-

cumin-induced apoptosis has also been studied in Caki cells, where curcumin causes apoptosis through down-regulation of Bcl-XL and IAP, release of cytochrome *c* and inhibition of Akt, which are markedly blocked by *N*-acetylcysteine, indicating a role of ROS in curcumin-induced cell death⁹⁶. In LNCaP prostate cancer cells, curcumin induces apoptosis by enhancing tumour necrosis factor-related apoptosis-inducing ligand (TRAIL)⁹⁷. The combined treatment of the cell with curcumin and TRAIL induces DNA fragmentation, cleavage of procaspase 3, 8 and 9, truncation of Bid and release of cytochrome *c* from mitochondria, indicating involvement of both external receptor-mediated and internal chemical-induced apoptosis in these cells⁹⁷. In colorectal carcinoma cell line, curcumin delays apoptosis along with the arrest of cell cycle at G₁ phase⁹⁸. Curcumin also reduces *P53* gene expression, which is accompanied with the induction of HSP-70 gene through initial depletion⁹⁸ of intracellular Ca²⁺. Curcumin also produces nonselective inhibition of proliferation in several leukaemia, nontransformed haematopoietic progenitor cells and fibroblast cell lines⁹⁹. That curcumin induces apoptosis and large-scale DNA fragmentation has also been observed in Vγ9Vδ2⁺ T cells through inhibition of isopentenyl pyrophosphate-induced NFκB activation, proliferation and chemokine production¹⁰⁰. Curcumin induces apoptosis in human leukaemia HL-60 cells, which is blocked by some antioxidants³⁵. Colon carcinoma is also prevented by curcumin through arrest of cell-cycle progression independent of inhibition of prostaglandin synthesis¹⁰¹. Curcumin suppresses human breast carcinoma through multiple pathways. Its antiproliferative effect is estrogen-dependent in ER (estrogen receptor)-positive MCF-7 cells and estrogen-independent in ER-negative MDA-MB-231 cells³⁷. Curcumin also downregulates matrix metalloproteinase (MMP)-2 and upregulates tissue inhibitor of metalloproteinase (TIMP)-1, two common effector molecules involved in cell invasion³⁷. It also induces apoptosis through *P53*-dependent Bax induction in human breast cancer cells³⁸. However, curcumin affects different cell lines differently. Whereas leukaemia, breast, colon, hepatocellular and ovarian carcinoma cells undergo apoptosis in the presence of curcumin, lung, prostate, kidney, cervix and CNS malignancies and melanoma cells show resistance to cytotoxic effect of curcumin¹⁰².

Curcumin also suppresses tumour growth through various pathways. Nitric oxide (NO) and its derivatives play a major role in tumour promotion. Curcumin inhibits iNOS and COX-2 production⁶⁹ by suppression of NFκB activation³⁴. Curcumin also increases NO production in NK cells after prolonged treatment, culminating in a stronger tumoricidal effect³³. Curcumin also induces apoptosis in AK-5 tumour cells through upregulation¹⁰³ of caspase-3. Reports also exist indicating that curcumin blocks dexamethasone-induced apoptosis of rat thymocytes^{104,105}. Recently, in Jurkat cells, curcumin has been shown to prevent glutathione depletion, thus protecting cells from caspase-3

activation and oligonucleosomal DNA fragmentation¹⁰⁶. Curcumin also inhibits proliferation of rat thymocytes¹⁰⁴. These strongly imply that cell growth and cell death share a common pathway at some point and that curcumin affects a common step, presumably involving modulation of AP-1 transcription factor^{104,106}.

Pro/antimutagenic activity

Curcumin exerts both pro- and antimutagenic effects. At 100 and 200 mg/kg body wt doses, curcumin has been shown to reduce the number of aberrant cells in cyclophosphamide-induced chromosomal aberration in Wistar rats¹⁰⁷. Turmeric also prevents mutation in urethane (a powerful mutagen) models¹⁰⁸. Contradictory reports also exist. Curcumin and turmeric enhance γ-radiation-induced chromosome aberration in Chinese hamster ovary¹⁰⁹. Curcumin has also been shown to be non-protective against hexavalent chromium-induced DNA strand break. In fact, the total effect of chromium and curcumin is additive in causing DNA breaks in human lymphocytes and gastric mucosal cells¹¹⁰.

Anticoagulant activity

Curcumin shows anticoagulant activity by inhibiting collagen and adrenaline-induced platelet aggregation *in vitro* as well as *in vivo* in rat thoracic aorta²³.

Antifertility activity

Petroleum ether and aqueous extracts of turmeric rhizomes show 100% antifertility effect in rats when fed orally⁴³. Implantation is completely inhibited by these extracts¹¹¹. Curcumin inhibits 5α-reductase, which converts testosterone to 5α-dihydrotestosterone, thereby inhibiting the growth of flank organs in hamster¹¹². Curcumin also inhibits human sperm motility and has the potential for the development of a novel intravaginal contraceptive¹¹³.

Antidiabetic effect

Curcumin prevents galactose-induced cataract formation at very low doses¹¹⁴. Both turmeric and curcumin decrease blood sugar level in alloxan-induced diabetes in rat¹¹⁵. Curcumin also decreases advanced glycation end products-induced complications in diabetes mellitus¹¹⁶.

Antibacterial activity

Both curcumin and the oil fraction suppress growth of several bacteria like *Streptococcus*, *Staphylococcus*, *Lactobacillus*, etc.¹⁵. The aqueous extract of turmeric rhizomes

has antibacterial effects¹¹⁷. Curcumin also prevents growth of *Helicobacter pylori* CagA⁺ strains *in vitro*¹¹⁸.

Antifungal effect

Ether and chloroform extracts and oil of *C. longa* have antifungal effects^{41,46,119}. Crude ethanol extract also possesses antifungal activity¹²⁰. Turmeric oil is also active against *Aspergillus flavus*, *A. parasiticus*, *Fusarium moniliforme* and *Penicillium digitatum*¹²¹.

Antiprotozoan activity

The ethanol extract of the rhizomes has anti-*Entamoeba histolytica* activity. Curcumin has anti-*Leishmania* activity *in vitro*¹²². Several synthetic derivatives of curcumin have anti-*L. amazonensis* effect¹²³. Anti-*Plasmodium falciparum* and anti-*L. major* effects of curcumin have also been reported¹²⁴.

Antiviral effect

Curcumin has been shown to have antiviral activity⁴. It acts as an efficient inhibitor of Epstein-Barr virus (EBV) key activator Bam H fragment z left frame 1 (BZLF1) protein transcription in Raji DR-LUC cells¹²⁵. EBV inducers such as 12-0-tetradecanoylphorbol-13-acetate, sodium butyrate and transforming growth factor-beta increase the level of BZLF1 m-RNA at 12–48 h after treatment in these cells, which is effectively blocked by curcumin¹²⁵. Most importantly, curcumin also shows anti-HIV (human immunodeficiency virus) activity by inhibiting the HIV-1 integrase needed for viral replication^{27,126}. It also inhibits UV light-induced HIV gene expression¹²⁷. Thus curcumin and its analogues may have the potential for novel drug development against HIV.

Antifibrotic effect

Curcumin suppresses bleomycin-induced pulmonary fibrosis in rats¹²⁸. Oral administration of curcumin at 300 mg/kg dose inhibits bleomycin-induced increase in total cell counts and biomarkers of inflammatory responses. It also suppresses bleomycin-induced alveolar macrophage-production of TNF- α , superoxide and nitric oxide. Thus curcumin acts as a potent antiinflammatory and antifibrotic agent.

Antivenom effect

Ar-turmerone, isolated from *C. longa*, neutralizes both haemorrhagic activity of *Bothrops* venom and 70% lethal effect of *Crotalus* venom in mice⁴. It acts as an enzymatic inhibitor of venom enzymes with proteolytic activities⁴⁷.

Pharmacokinetic studies on curcumin

Curcumin, when given orally or intraperitoneally to rats, is mostly egested in the faeces and only a little in the urine^{129,130}. Only traces of curcumin are found in the blood from the heart, liver and kidney. Curcumin, when added to isolated hepatocytes, is quickly metabolized and the major biliary metabolites are glucuronides of tetrahydro-curcumin and hexahydrocurcumin^{131,132}. Curcumin, after metabolism in the liver, is mainly excreted through bile.

Clinical studies and medicinal applications of turmeric and curcumin

Although various studies have been carried out with turmeric extracts and some of its ingredients in several animal models^{1,4,133}, only a few clinical studies are reported so far.

Turmeric

Powdered rhizome is used to treat wounds, bruises, inflamed joints and sprains¹³⁴ in Nepal. In current traditional Indian medicine, it is used for the treatment of biliary disorders, anorexia, cough, diabetic wounds, hepatic disorders, rheumatism and sinusitis⁴⁸. Data are also available showing that the powder, when applied as capsules to patients with respiratory disease, gives relief from symptoms like dyspnoea, cough and sputum¹³⁵. A short clinical trial in 18 patients with definite rheumatoid arthritis showed significant improvement in morning stiffness and joint swelling after two weeks of therapy with oral doses of 120 mg/day⁵³. Application of the powder in combination with other plant products is also reported for purification of blood and for menstrual and abdominal problems¹³⁶.

Curcumin

In patients undergoing surgery, oral application of curcumin reduces post-operative inflammation¹³⁷. Recently, curcumin has been formulated as slow-release biodegradable microspheres for the treatment of inflammation in arthritic rats¹³⁸. It is evident from the study that curcumin-biodegradable microspheres could be successfully employed for therapeutic management of inflammation¹³⁸.

Safety evaluation with turmeric and curcumin

Detailed studies have been reported on the safety evaluation of the rhizomes of *C. longa* and its alcohol extract, curcumin^{132,139}. The major findings are presented below.

Turmeric

The average intake of turmeric by Asians varies from 0.5 to 1.5 g/day/person, which produces no toxic symptoms².

Male and female Wistar rats, guinea pigs and monkeys were fed with turmeric at much higher doses (2.5 g/kg body wt) than normally consumed by humans. No changes were observed in the appearance and weight of kidney, liver and heart¹³². Also, no pathological or behavioural abnormalities were noticed and no mortality was observed.

Curcumin

Curcumin was given to Wistar rats, guinea pigs and monkeys of both sexes at a dose of 300 mg/kg body wt. No pathological, behavioural abnormalities or lethality was observed¹³³. No adverse effects were observed on both growth and the level of erythrocytes, leucocytes, blood constituents such as haemoglobin, total serum protein, alkaline phosphatase, etc.¹³⁹. Human clinical trials also indicate that curcumin has no toxicity when administered at doses of 1–8 g/day¹⁴⁰ and 10 g/day¹⁴¹.

Future prospects

Turmeric has been used in ayurvedic medicine since ancient times, with various biological applications. Although some work has been done on the possible medicinal applications, no studies for drug-development have been carried out as yet. Although the crude extract has numerous medicinal applications, clinical applications can be made only after extensive research on its bioactivity, mechanism of action, pharmacotherapeutics and toxicity studies. However, as curcumin is now available in pure form, which shows a wide spectrum of biological activities, it would be easier to develop new drugs from this compound after extensive studies on its mechanism of action and pharmacological effects. Recent years have seen an increased enthusiasm in treating various diseases with natural products. Curcumin is a non-toxic, highly promising natural antioxidant compound having a wide spectrum of biological functions. It is expected that curcumin may find application as a novel drug in the near future to control various diseases, including inflammatory disorders, carcinogenesis and oxidative stress-induced pathogenesis.

Origin of agriculture and domestication of plants and animals linked to early Holocene climate amelioration

Anil K. Gupta

Department of Geology and Geophysics, Indian Institute of Technology, Kharagpur 721 302, India

Domestication of plants and animals was necessary for the evolution of agriculture, spatial expansion and population increase of humans during the Holocene, which facilitated the evolution of technically innovative societies. The agricultural practices enabled people to establish permanent settlements and expand urban-based societies. Domestication of plants and animals transformed the profession of the early humans from hunting and gathering to selective hunting, herding and settled agriculture. The earliest archaeological evidences, found throughout the tropical and subtropical areas of southwestern and southern Asia, northern and central Africa and Central America, suggest rapid and large-scale domestication of plants and animals ca. 10,000–7000 cal years BP. This interval corresponds to an intense humid phase and equable climates, as observed in numerous paleo records across the regions. I suggest that domestication of plants and animals and subsequent beginning of agriculture were linked to climate amelioration in the early Holocene.

CLIMATE has played a critical role in the evolution of fauna and flora. Proxy data suggest occurrence of widespread repeated, abrupt climate changes throughout the geological record¹. Persistent abrupt changes in climate may alter ecological landscape, leading to faunal adaptation. Human adaptation and migration in response to severe climate changes are known from the paleo records². Recent archaeological findings from Yana River, Siberia, indicate that humans adapted to the harsh, frigid climate of the Arctic during the late Pleistocene about 27,000 year ago³. Likewise, they adapted to arid conditions in the Thar⁴ and Sahara Deserts⁵ in the late Holocene. Although some human societies have adapted to rapid climate changes in the past, there are also examples of civilizational collapse under the persistent influence of climate change. The collapse of the Akkadian, Classic Maya, Mochica and Tiwanaku was related to persistent multi-century shifts in climate^{6,7}. The rise and fall of human civilizations in South Asia have also been climatically mediated⁸. The effect of persistent abrupt climate changes has been equally drastic on the

flora, that brought shifts from one type to another type of vegetation in the past geological records⁹.

The anthropogenic pressures in response to climate change have brought significant changes in fauna and flora. The most significant examples of human impact on the evolution of ecological niches come from domestication of animals and plants. Domestication refers to the process of reciprocation, by which animal and plant species come to depend on humans for survival, while providing humans with numerous benefits in turn. The process of domestication has been markedly important for spatial expansion and population increase of humans during the Holocene. Domesticated plants and animals are of prime importance for agriculture. Without agriculture, the complex, technically innovative societies and large human populations that exist today could not have evolved. Agriculture allowed people to become sedentary (living for a prolonged period in one place), establish permanent villages and towns and develop classified societies that included specialized and dedicated segments such as farmers, artisans, soldiers, religious leaders, teachers and governors. Agriculture is thus defined as the cultivation of domesticated plants and animals for use by the human societies, as many domesticated plants and animals would not survive without human intervention¹⁰.

Early hominids were hunters and gatherers who relied on naturally occurring vegetation, fruits, nuts, carrion and game for subsistence. Hunters and gatherers do not establish permanent settlements such as villages. They move their camps in response to changes in the season and climate. Subsistence by hunting and gathering is still practised by ancient tribes throughout the world. As the climate ameliorated, there was an increase in vegetation and people changed their food habits and lifestyle. Dogs were the first to have been domesticated by early humans (Table 1)¹⁰, which might have been used for hunting of wild animals. Goats and sheep were next to have been domesticated in southern and southwestern Asia during the early Holocene^{8,10,11}. The remains of sheep and goats found at hominid sites that are older than about 10,000 cal years show no evidence of domestication¹⁰, suggesting that hunters were killing the whole population of goats and sheep at that time. However, there was a shift towards greater abundance of skeletons of younger goat and sheep at hominid
